TECHNICAL MEMORANDUM

DATE: October 5, 2016
TO: Bob Egan, SME, EPA Region 5
FROM: Matt Faust, Project Manager
Bristol Environmental Remediation Services, LLC
RE: EPA Contract No. EP-W-12-009, Task Order (TO) 3012
Tower Standard Site, Lac du Flambeau Reservation, Wisconsin
Corrective Action Recommendations, Revision 0

The U.S. Environmental Protection Agency (EPA) retained Bristol Environmental Remediation Services, LLC (Bristol) to prepare this technical memorandum (tech memo) under EPA Contract EP-W-12-009, Task Order (TO) 3012. This tech memo describes the potential remedial alternatives for consideration at a leaking underground storage tank (LUST) site in Lac du Flambeau, Wisconsin, on the Lac du Flambeau (LDF) Reservation (Figure 1) as well as the results of modeling activities. The site is referred to as the Tower Standard Site.

BACKGROUND

The State of Wisconsin's Petroleum Environmental Cleanup Fund Award (PECFA) contractor performed a membrane interface probe (MIP)/hydraulic profiling tool investigation at the site between July 11 and 14, 2016. The LDF Tribe performed a laser-induced fluorescence (LIF) investigation at the site on September 7 and 8, 2016. Bristol has contracted with S₂C₂, Inc. (S₂C₂) of Raritan, New Jersey, to generate a three-dimensional model of the contaminant plume at the site, incorporating data collected during the MIP and LIF investigations, as well as soil and groundwater analytical data. The results of the S₂C₂ modeling are presented in a report in Attachment 1.

Groundwater at the site is approximately eight feet below ground surface (bgs) in the area where soil contamination is present. This depth corresponds to an elevation of 1,568 feet above mean sea level (msl). The groundwater flow direction at the site is generally towards the south-southeast (at the water table) or south-southwest (at depth) (Bristol, 2016a). The extent of contamination towards the northwest (cross-gradient) is fairly well defined. The extent of contamination to the northeast (up-gradient), east (cross-gradient), and south (down-gradient) remains poorly defined.

The USTs and associated piping and dispensers have been removed and a groundwater extraction treatment system that operated for a time was also removed. During the operation of the groundwater extraction system, the water levels in nearby monitoring wells lowered by 3 to 4 feet bgs. The depth to groundwater on the site during this time was approximately 12 feet bgs. Data is not available on the specific operation of the groundwater extraction system. Petroleum hydrocarbons remain in the soil at the site, and are the source of the dissolved phase groundwater contamination.

SOURCE AREA SOIL EXTENT

The extent of the soil source area has been evaluated using soil sample results collected in 2015 and 2016, as well as the MIP and LIF investigations. The MIP data detects volatile compounds in soil and groundwater. The LIF data only represents petroleum hydrocarbons sorbed on soil particles and does not detect dissolved phase petroleum hydrocarbons.

Review of the available data and the S₂C₂ report shows that petroleum impacted soils are present from near the ground surface to depths of 12 feet bgs. Figure 6 of the S₂C₂ report in Attachment 1, represents the area of petroleum hydrocarbon impacted soils. There are areas where shallow soil contamination is present. This shallow contamination is present from near the ground surface to the groundwater table at 8 feet bgs. The shallow contamination is

not widespread or localized. This shallow contamination impacts groundwater only as precipitation infiltrates through the soil to the groundwater. Areas of shallow soil contamination are shown on Figure 2.

The largest area of soil contamination is present in the smear zone soil from a depth of 8 to 12 feet bgs, or an elevation from 1,568 to 1,564 feet above msl. This zone represents the largest mass and volume of petroleum impacted soils that directly impact the groundwater contamination. Figure 3 presents the approximate extent of the smear zone soil contamination. Review of individual LIF logs and S₂C₂ model cross sections show that the vertical extent of soil contamination below the water table is not vertically continuous. Soil contamination may be present in thin discrete layers with contamination present from 8 to 9 feet bgs and 11 to 12 feet bgs. The area of heavily contaminated soil covers an area measuring approximately 40 by 90 feet or 3,600 square feet.

The S₂C₂ report presents estimates of the volume of impacted soil based on relative sensor readings from the MIP and LIF work. The total volume based on both MIP and LIF data range from 4,800 to 78,000 cubic yards (cy) of soil. This large difference is primarily due to the MIP data being collected over a larger area and including both soil and groundwater contamination, while the LIF data only includes soil contamination focused on the source area. The S₂C₂ report presents volume estimates based on LIF data for various LIF response ranges (see Tables 1a-1c). The volume for the highest response range (highest contamination) is 25 cy. The LIF data can be used to target specific areas of highest contamination.

REMEDIAL ALTERNATIVES

The soil source area remedial alternatives focus on both the shallow vadose zone and the smear zone. Remedial technologies include excavation and either disposal, treatment, or in situ treatment.

The shallow vadose zone soils are readily treated by excavation and disposal. The contamination present at the water table can also be excavated and disposed of. The contamination present in the smear zone below the water table may be excavated, or in situ treatment may be required. In situ treatment options include air sparging (AS) and soil vapor extraction (SVE). Air sparging works by blowing air into the groundwater, which supplies oxygen to stimulate biodegradation and removes VOCs through volatilization. The air containing the VOC is then collected in the vadose zone by SVE. The vapors then may be treated and discharged to the atmosphere. The deeper soils may also be treated by chemical oxidation. This requires the injection of a chemical oxidant that destroys the contaminants. Chemical oxidation typically requires multiple injection events and can be highly effective at treating deeper, isolated hot spots that may not have been removed by excavation.

The following is a discussion of remedial options that may be implemented at the site. Order of magnitude costs are also presented to allow for a relative comparison.

OPTION 1

Option 1 consists of excavation and disposal of shallow contaminated soil. The soil would be excavated and trucked to the Lincoln County landfill. There is an area of approximately 1,200 square feet (including 360 cubic yards [cy] of excavated soil) where shallow contamination is present from near the ground surface to the water table. Assuming half of this is clean overburden then 180 cy would require disposal. The estimated cost for option 1 is \$30,000.

OPTION 2

Option 2 consists of excavation and disposal of smear zone contaminated soil. The soil would be excavated to a depth of approximately 1 to 2 feet below the water table. Clean overburden would need to be excavated over a large portion of the area. Saturated soils may require time

to drain prior to transportation to the Lincoln County landfill. The water would have to be collected and treated on site and either allowed to infiltrate or be hauled off site for disposal. This assumes there is an area of 3,600 square feet with a depth of excavation to 9 feet bgs. The volume of soil from 6 to 9 feet bgs over this area is 400 cy. This combined with the 180 cubic yards removed in Option 1 is a total of 580 cy. The estimated cost for this option is \$90,000.

OPTION 3

Option 3 consists of excavation and disposal of smear zone contaminated soil. The soil would be excavated to a depth of approximately 3 to 4 feet below the water table. This option will require dewatering of the excavation. The saturated soils may need to be drained prior to transportation to the landfill. All water generated would have to be collected and treated on site and either allowed to infiltrate, be pumped into Haskell lake, or be hauled off site for disposal. This assumes an area of 3,600 square feet with a depth of excavation to 12 feet bgs. The volume of soil from 9 to 12 feet bgs over this area is 400 cy. This combined with the 580 cubic yards removed in Options 1 and 2, total 980 cy. The estimated cost for this option is \$150,000. This estimate does not include additional costs associated with handling of water.

OPTION 4

Option 4 consists of installation of an AS/SVE system. A pilot study is recommended to evaluate the radius of influence of the air sparge wells and SVE wells. Another concern at this site is the potential for fouling due to the interaction of oxygen with the aquifer and the geochemical interaction with the iron present in the aquifer. Also given the shallow groundwater horizontal SVE wells would likely be required. Assuming an air sparge well radius of influence of 10 feet and an area of 3,600 square feet, 12 sparge points would be required. The remediation timeframe would be two years or longer. The design and

installation of the system may cost \$160,000 with annual operating costs, including monitoring and maintenance, being \$50,000. Based on a two year treatment time the total cost would be \$260,000.

OPTION 5

Option 5 consists of application of a chemical oxidant. A pilot study is recommended to evaluate the most efficient oxidant. The pilot study cost would be approximately \$10,000. The cost to treat an area 20 by 20 feet or 400 square feet consisting of three injections is \$33,000. This is assuming that the target treatment zone is from 8 to 12 feet bgs and the average petroleum hydrocarbon concentration is 2,000 milligrams per kilogram (mg/kg) for a mass of 320 pounds of petroleum hydrocarbon. The estimated cost to treat an area of 3,600 square feet is \$300,000. The three injections could occur every six weeks with a total remediation timeframe of six months.

DISCUSSION OF OPTIONS

Options 1 and 2 are the simplest of the options to carry out, but will not remove all the source area soil. Option 3 may allow removal of all the soil beneath the water table, but may not be feasible across the entire site. Excavation in areas where monitoring wells exist may require limiting the excavation so the monitoring wells are not destroyed, or removing and replacing the wells. The uncertainty associated with options 4 and 5 is the concentration or mass of petroleum hydrocarbons to be treated. A larger mass will require additional time for AS/SVE and additional oxidant for Option 5. The largest unknown in all the options is where to treat. The options are not exclusive but can be combined. For instance, excavation and disposal can be followed by in situ treatment targeted at remaining deeper hot spots of contamination.

CONCLUSIONS

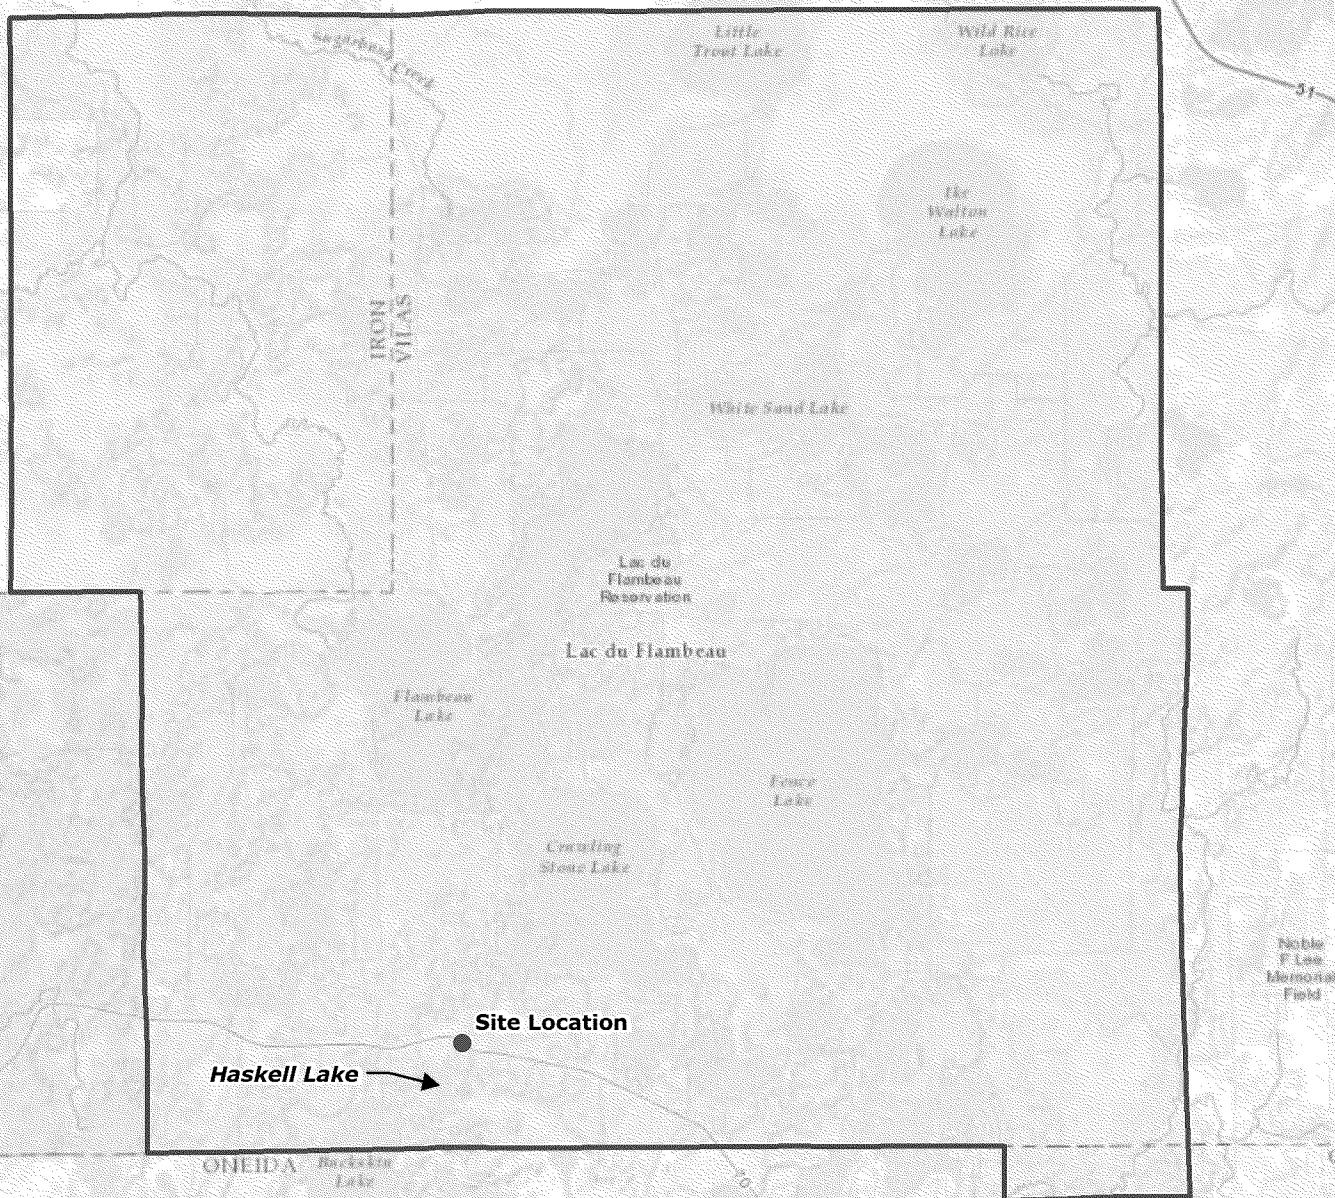

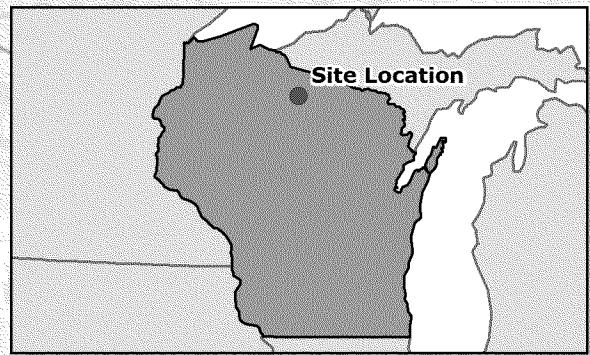

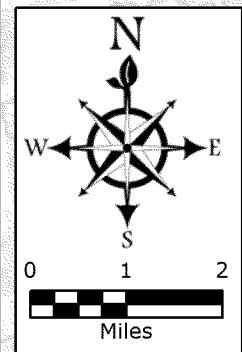

Each remediation option will remove mass from the subsurface and decrease the time for the dissolved phase groundwater plume to dissipate. The costs presented in this tech memo are based on the stated assumptions. Additional refinement of the S₂C₂ model can be performed to identify the volume of shallow soil and the volume of deeper soils in particular areas. This is important for all the options. The model refinements can also be combined with past analytical data to refine the mass estimate. The refined mass estimates are important for Options 4 and 5.

A phased approach to reducing contaminant mass contributing to the groundwater plume is recommended. This would include excavating contaminated shallow soil along with excavation in other identified areas of high contamination at or below the water table. Other identified hot spots could be targeted with chemical oxidation.

Introduction

Bristol Environmental Remediation Services (Bristol) contracted S₂C₂, Inc. (S₂C₂) to provide data analysis and data visualization services for data collected as part of a High Resolution Site Characterization (HRSC) field program conducted at the Tower Standard Site (Site) located in Lac du Flambeau, Wisconsin. HRSC data were collected using Geoprobe®'s combination Membrane Interface Probe-Hydraulic Profiling Tool (MiHPT) and electrical conductivity (EC) technologies . In addition, laser induced fluorescence (LIF) data were collected during a second mobilization using Dakota Technologies Ultra Violet Optical Screening Tool (UVOST). Data associated with this investigation were provided to S₂C₂ via electronic deliverables. All data were processed using a combination of software applications including ESRI's ArcGIS and Ctech's Earth Volumetric Studio Software (Studio). The objective of this data analysis and data visualization was to develop an updated Conceptual Site Model (CSM) for the Site to assist in the evaluation of Remedial Options.

Description of Data and Data Processing

Direct-sensing data were provided as raw Geoprobe MiHPT zip files , UVOST text files, and as excel summary tables and survey data from existing project data files . Prior to processing the data sets in Studio, MiHPT raw data files were evaluated in Geoprobe's DI Viewer Software to evaluate overall detector responses and HPT dissipation test results . MiHPT data were exported directly from DI Viewer to an excel worksheet. This worksheet was then used to export data files for use in Studio and ArcGIS. UVOST data were also exported from the raw text files to an Excel worksheet and formatted for Studio. Based on the evaluation of the data in DI Viewer, the following data sets were processed in Studio:

- Electrical Conductivity
- Corrected HPT Pressure
- HPT Estimated K values
- FID Detector Responses
- PID Detector Responses
- UVOST Fluorescence

In order to compare MIP detector data sets from individual boreholes, baseline and detector responses were evaluated. Figure 1 presents PID pre-test response test results for each MiHPT boring. Variability of pre-test and post-test responses was within typical ranges for MiHPT data so no baseline corrections were completed on the MiHPT data sets.

UVOST fluorescence data is reported relative to a reference emitter (%RE). This is calculated by dividing the total area of the waveform by the total area of the Reference Emitter. This %RE scales with the NAPL fluorescence. All location data were provided in North American Datum 1983 (NAD83) – Wisconsin Universal Transverse Mercator (UTM) coordinate system and National American Vertical Datum 1988 (NAVD 88) for elevations. Locations were projected to NAD83 Wisconsin State Plane North since Studio does not support Wisconsin UTM coordinate system (horizontal coordinates only).

Once all direct-sensing data were exported from DI Viewer and locations projected as described above, direct-sensing data were processed using Ctech's Data Reduction Tool. Due to the high density nature of direct-sensing data in the z-axis (20 recorded values for every 1 ft of depth) as compared to the density on x- and y- axes, 3D kriging of data oversampled in the z-direction may produce unacceptable artifacts and require very high computing resources during kriging. To reduce the occurrence of these artifacts, the Data Reduction Tool is able to assist in selecting the most critical data points (i.e. the max/min points) and preserve them while omitting the less critical data points by using a number of reduction options. The purpose of this data reduction is to reduce the number of data to less than 6,000 so that all data can be used during kriging. In addition to targeting a final data set with no more than 6,000 points, the operator will select a data density that is approximately equal to the vertical grid resolution. This will reduce vertical averaging of data points during the kriging routine. All data sets were reduced using gradient optimization (HPT Pressure and Estimate K data sets) or the max of samples (MIP-PID and MIP-FID data) data reduction options. A summary of data file statistics for all visualized data sets is provided in Attachment 1 and a copy of final data files are provided in Attachment 2.

Geologic Interpretation and Grid Development

Geologic materials at the Site are described as primarily sands with some large cobbles and boulders that were deposited in a glacial depositional environment. HPT pressure data is consistent with this interpretation and will be used as an indicator of geologic conditions.

A simple rectilinear grid (Figure 2) was created in Studio for use in kriging. The grid consists of 8,100 five foot by five foot cells. Surfaces for topography, the estimated top of water table calculated from MiHPT borings and an arbitrary bottom set at an elevation of 1509 ft msl were kriged within the grid utilizing Studio's Krig3DGeology kriging algorithm. MiHPT and UVOST locations are presented on Figures 2 and 3, respectively.

Direct Sensing Data Kriging

Once the geologic model was finalized and direct-sensing data were reduced, all data were individually kriged using Studio's 3Dkriging module within the geologic grid described above using a z resolution of 120 cells. Kriging settings were set individually for each data set based on individual data properties. Grid node values were calculated in MVS utilizing an ordinary kriging algorithm using all data points with a spherical semivariogram and zero nugget. A summary of data statistics and kriging parameters are provided in Attachment 3.

In order to evaluate variability in predicted values from the kriging results, PID, FID and UVOST detector data were kriged using Ctech's min/max kriging option with a confidence level of 80% and a confidence bound factor of 10. This option reports the minimum,

median, and maximum predicted value of possible calculated values that have a calculated confidence of 80% within the confidence bound factor (i.e. the minimum, median, and maximum predicted value that has a calculated confidence that is within one order of magnitude of the actual value). The results of this analysis can show variability of predicted values and are particularly useful for chemical data sets.

In addition to the 3D kriging described above, 2-dimensional (2D) kriging was conducted on the full 3D analytical data sets in order to create 2D maximum outputs for the FID, PID and UVOST data. Please note that there is actually no interpolation complete d in these calculations and as such there are no exported statistics (i.e. confidence is always 100%). The 3D data sets are collapsed by the maximum value and then kriged in 2D. Since the nodes of the collapsed 3D data set match the 2D grid, the predicted value is simply the maximum value of the 3D data.

In order to help control boundary conditions for the MIP -FID and MIP -PID kriging, six control points were added to the data set. Four control points were created based on groundwater data from groundwater samples collected at MW-2, MW-3, MW-17 and MW-18. For these locations, FID and PID responses of 1,000 uV were inserted at one foot intervals throughout the well's screened interval. In addition to these control points, two additional locations were added to the east and southeast of the Site. At these locations FID and PID responses of 10,000 uV were added from 0 to 24 bgs. See attached data files for details on the control points.

3-Dimensional Conceptual Site Model

In order to illustrate the final 3D-CSM, three 4-D Interactive Model Player (4DIM) files were created and are available electronically. Viewing the 4DIM visualization files requires C Tech Corporation's Standalone 4D Interactive Model Player freeware and is available at <http://client.ctech.com/> (see "Standalone 4DIM Player Installation").

4Dim exports were created from the MVS results and include the following:

1. Tower_HRSC_CSM_FID2016.4d
2. Tower_HRSC_CSM_PID2016.4d
3. Tower_HRSC_CSM_LIF2016.4d

In addition, the following figures were created to present the results of the 3D CSM:

- Figure 4: MIP-FID Response 2D Maximum
- Figure 5: MIP-PID Response 2D Maximum
- Figure 6: UVOST-LIF Response 2D Maximum
- Figure 7: MIP-FID Fence with HPT-Estimated K
- Figure 8: MIP-PID Fence with HPT Estimated K

Figure 9: UVOST-LIF Fence with MIP-FID

Figure 10: UVOST-LIF Fence with MIP-PID

Volumetric and Mass Analysis

Volumetric analysis was completed for the FID, PID, and UVOST detector data based on subsetting by the individual responses. A summary of the volumetric analysis results is presented below. The calculated volumes represent the soil volume within the plume shell where the kriged detector data exceeds the chosen threshold value. The average response is the calculated average for all nodes within the given plume shell. Mass calculations were not provided since the direct sensing detector data are not actual concentrations.

FID Response Range (uV)	Total Soil Volume (cu. Yards)	Average FID Response (uV)
>1,000,000	1,600	2.97e6
>500,000	3,300	1.81e6
>100,000	32,700	3.47e5
>50,000	78,000	1.85e5

Table 1a: Summary of soil volume with varying FID responses.

PID Response Range (uV)	Total Soil Volume (cu. Yards)	Average PID Response (uV)
>1,000,000	880	1.71e6
>500,000	2,200	1.10e6
>100,000	25,200	2.68e5
>50,000	70,000	1.38e5

Table 1b: Summary of soil volume with varying PID responses.

LIF Response Range (%RE)	Total Soil Volume (cu. Yards)	Average LIF Response (%RE)
5.0	25	9.78
2.0	195	3.90
1.0	950	1.89
0.4	4,800	0.8

Table 1c: Summary of soil volume with varying LIF responses.

Quality Assurance and Quality Control (QA/QC)

This section provides a brief description of data usability and QA/QC procedures followed during data processing and data visualization. Quality control was applied throughout the

data visualization process from data assimilation through data visualization. This included data export controls (Scribe database), evaluating data statistics, evaluating grid resolution, integrated team evaluation of geologic interpretation, and evaluating individual components of the visualization as well as collaborative data sets.

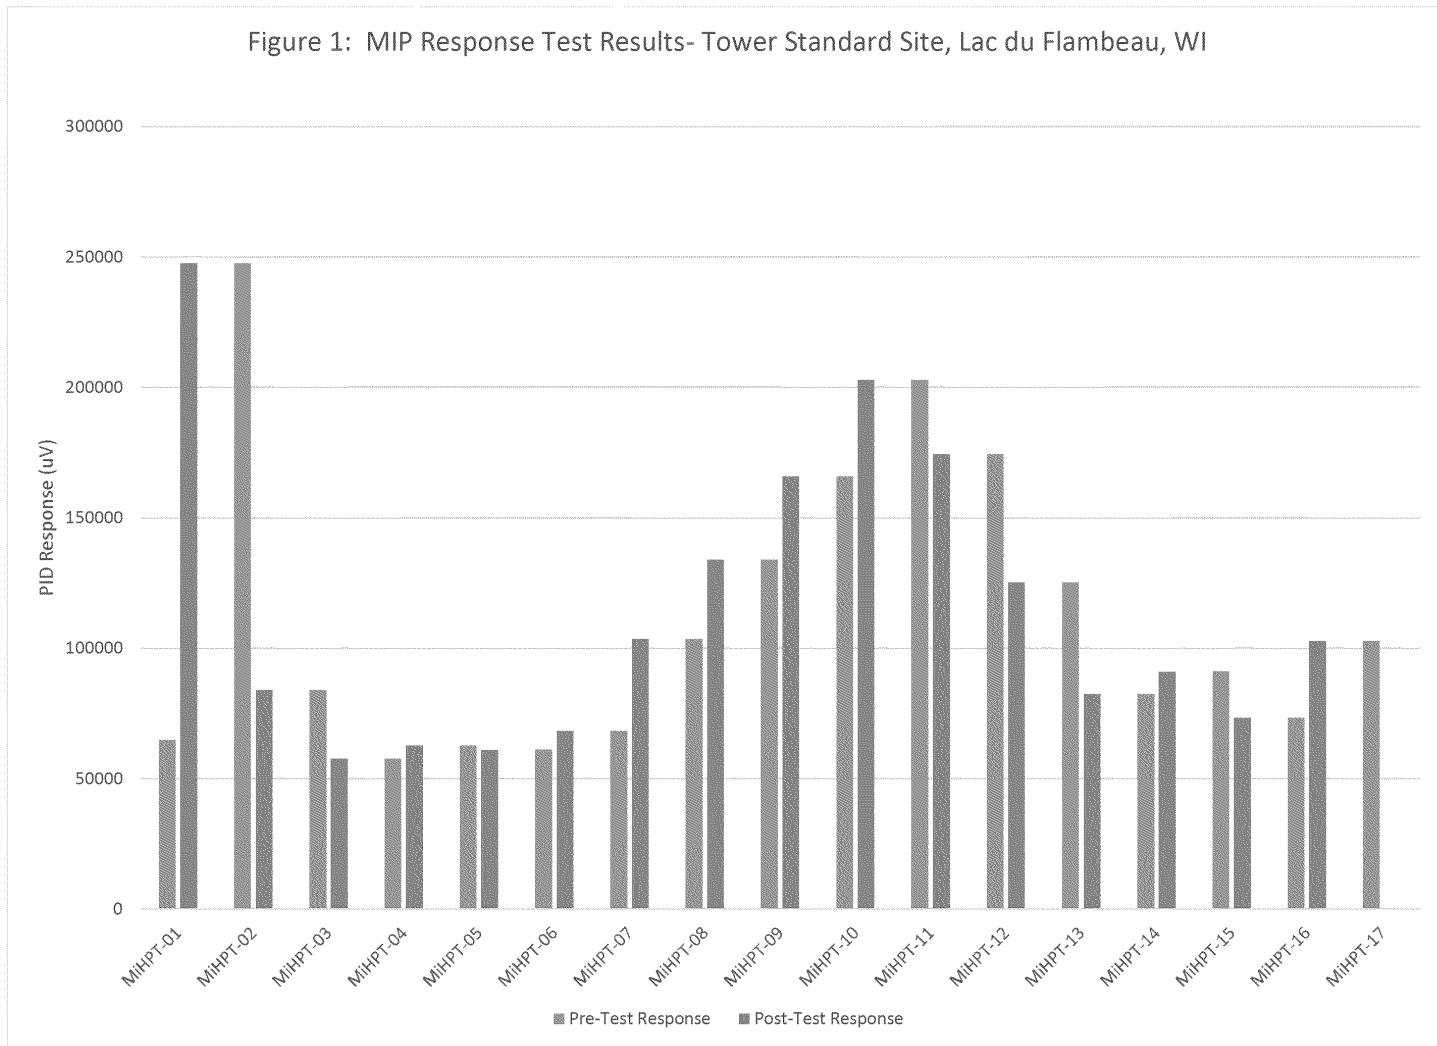

All direct-sensing data were exported directly from Geoprobe's DI Viewer software or directly from exported raw files (UVOST Data). This data set was then processed through Ctech's data reduction tool. This process was implemented to limit any had modifications to the direct-sensing data. Any modifications to the data sets are recorded as notes in the data files.

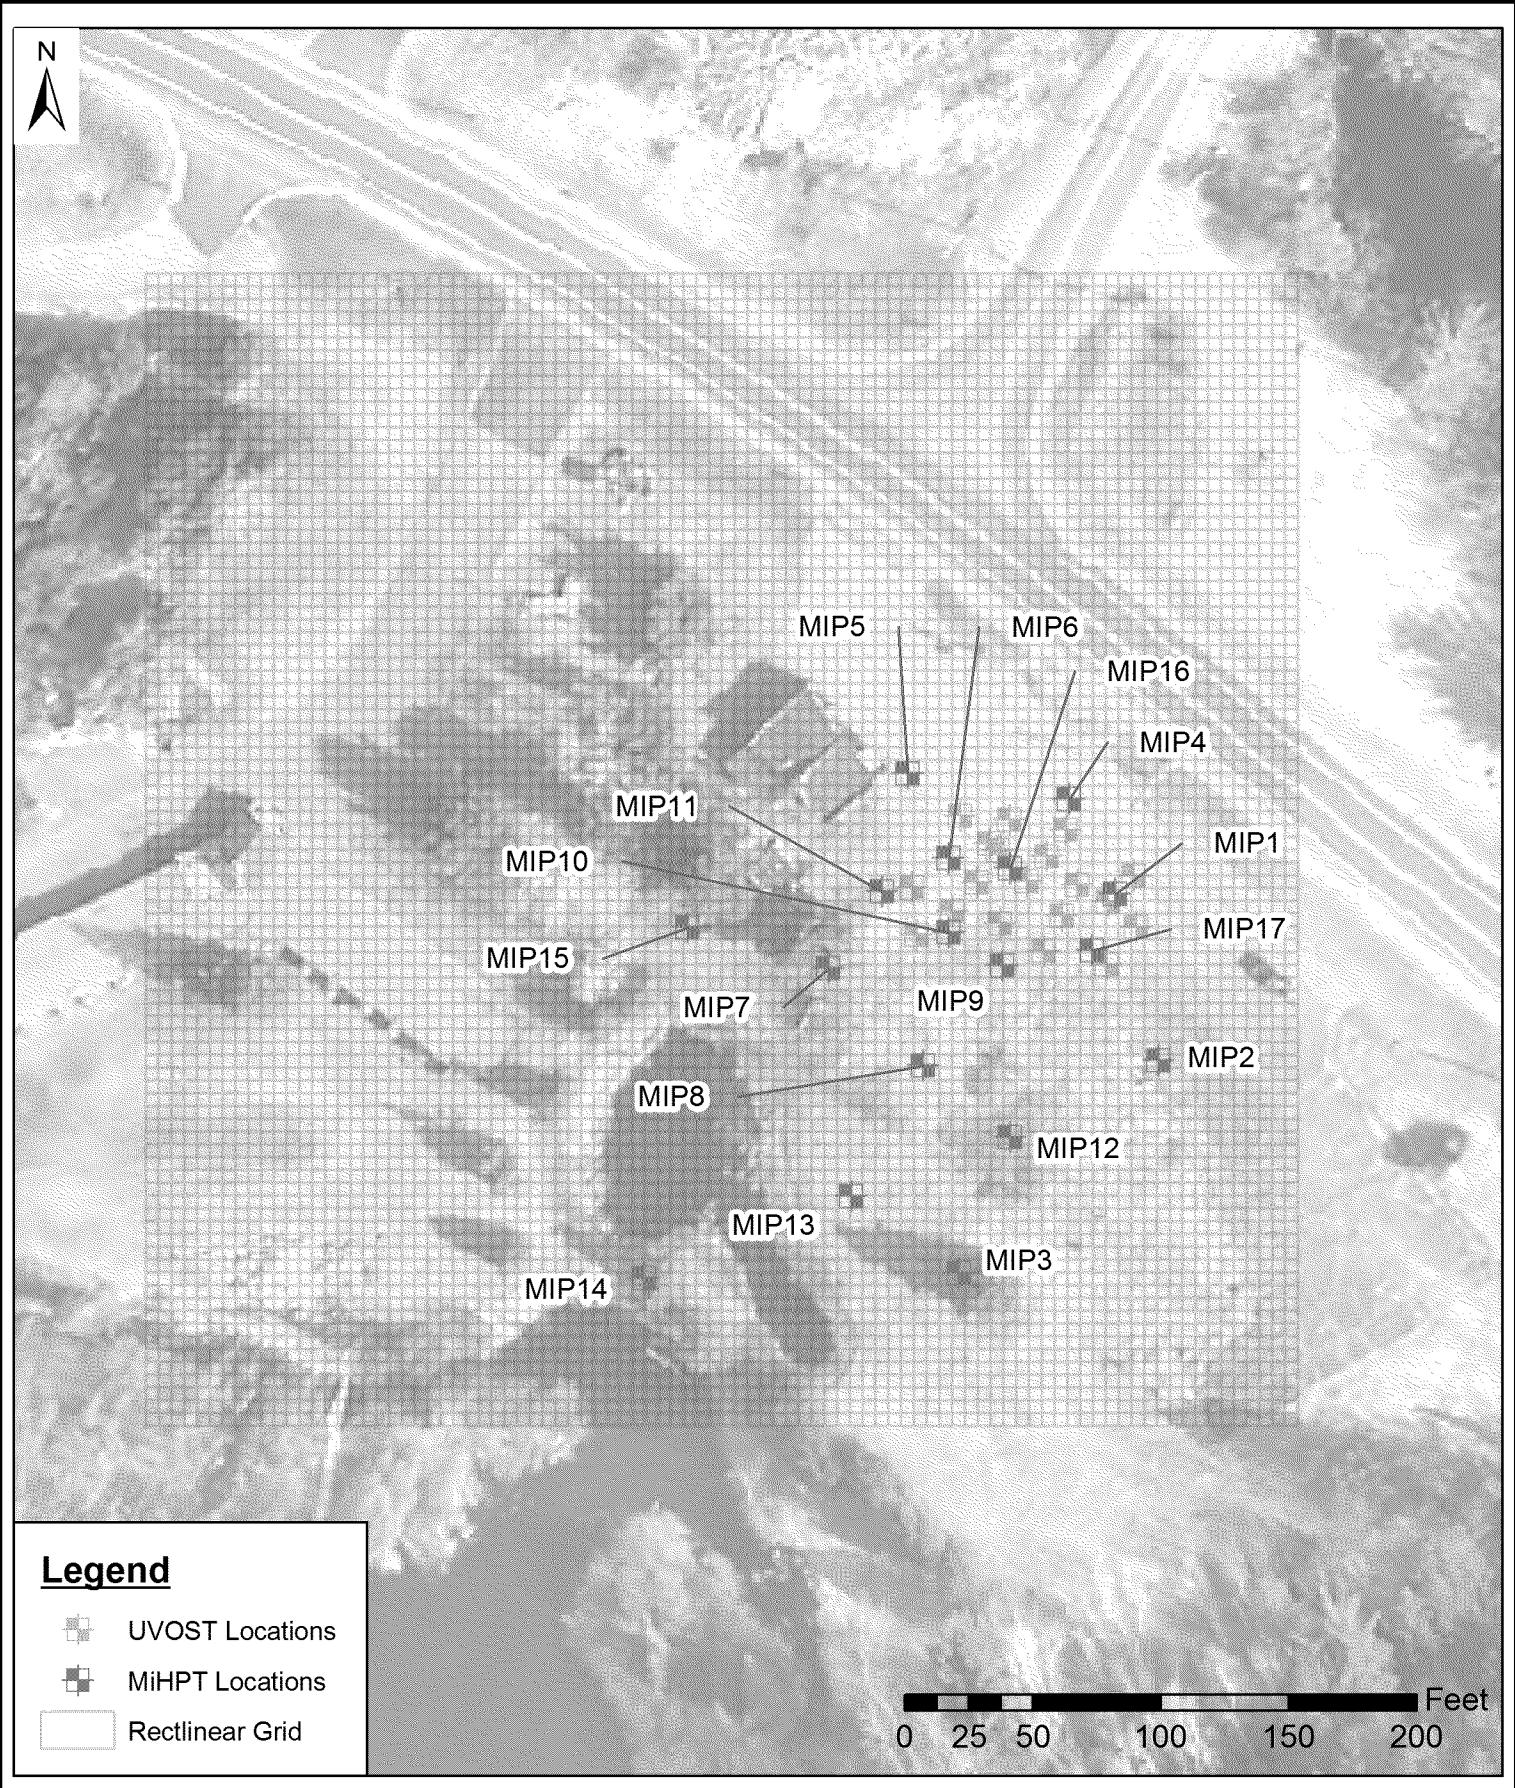

As discussed in the direct-sensing and analytical kriging section above, the direct sensing and analytical data sets were kriged individually within the final geologic grid. Individual kriging parameters and data statistics are summarized in Attachments 1,2, and 3. Ctech's kriging algorithm provides statistical confidence for each predicted value calculated during the kriging routine in addition to min-max kriging was completed for the analytical data sets to evaluate minimum and maximum predicted values. For all data sets the confidence of the predicted values is high in the vicinity of the data. Predicted values away from the data will tend to approach the median value of the data and have a low confidence. This is especially evident in the direct-sensing kriging results due to the more limited aerial extent of the data.

Overall, the kriged data provide predicted values within the geologic grid that can be used to evaluate collaborative data sets in a visual 3 -dimensional platform. As with any predictive tool, the statistical confidence of the results is a function of the data density. Based on the collaborative nature of the data evaluated for this Site, the final kriged data sets provide a useful tool for evaluating, updating and confirming the Conceptual Site Model for the Tower Standard Site.

FID Kriging Settings (Ordinary Kriging):
 Data are log processed
 Pre-Clip Min: 1,000 uV
 Pre-Clip Max: 10,000,000 uV
 Post-Clip Min/Max: Same as above.
 Gridding: Proportional
 Interpolation: Min-Max Plume
 Used all data points. Range and Points not set.
 Min-Max Plume Confidence: 80%
 Horizontal/Vertical Anisotropy: 15.0

Kriged FID Data Set (uV)

Field has 1002001 MIP-FID nodes and 963900 cells
 X Min: 1990300.1599 X Max: 1990750.0000 Extent: 449.8401
 Y Min: 272200.0000 Y Max: 272650.0000 Extent: 450.0000
 Z Min: 1509.0000 Z Max: 1577.6276 Extent: 68.6276
 Centroid of model X: 1990525.0800 Y: 272425.0000 Z: 1543.3138

Statistics for 1002001 values in 10 bins.
 Mean: 8014.5932 Median: 8181.2762 Data Min: 1000.0000 Data Max: 10000000.0000

Variance(log)= 0.5396 Std. Dev. (log)= 0.7346

1st Quartile = 1203.4912 3rd Quartile = 32514.6973

Data Range = 9999000.0000 Interquart. Rng= 31311.2062

Bin	Min	Max	Counts	Percent
1	1000.0000	2511.8864	334743	33.41
